1 Introduction

The success of constraint programming in expressing and solving hard real-world problems has created an increasing demand for more flexible and application-oriented customization of constraint solvers. The declarative language Constraint Handling Rules (CHR) [Frü98] is a successful proposal especially designed for the executable specification of user-defined constraints.

In this paper we present a finite domain solver written in CHR, which performs hard and soft constraint propagation. Hard constraints are conditions that must be satisfied, soft constraints, however, may be violated, but should be satisfied as much as possible. The solver is powerful enough to serve as the core of a university timetabling system.

Then we show that a small and simple extension to CHR makes it a general-purpose constraint logic programming language. The extended language, called “CHR⁺”, turns out to be a very flexible query language since it supports several (constraint) logic programming paradigms and allows to mix them in a single program. In particular, it supports top-down query evaluation and also bottom-up evaluation as it is frequently used in (disjunctive) deductive databases.

2 Constraint Handling Rules

Constraint Handling Rules (CHR) [Frü98] is a declarative high-level language extension especially designed for writing constraint solvers. With CHR, one can introduce user-defined constraints into a given host language, be it Prolog, Lisp or any other language.

2.1 Syntax and Semantics

A constraint is a first order atomic formula. We use two disjoint sorts of predicate symbols for two different classes of constraints: One sort for built-in constraints and one sort for user-defined constraints. Built-in constraints are those handled by a predefined constraint solver that already exists. User-defined constraints are those defined by a CHR program.

A CHR program is a finite set of rules. There are two basic kinds of rules.

A simplification rule is of the form \( H \leftrightarrow C \mid B \) and a propagation rule is of the form \( H \Rightarrow C \mid B \), where the head \( H \) is a non-empty conjunction of user-defined constraints, the guard \( C \) is a built-in constraint and the body \( B \) is a conjunction of built-in and user-defined constraints. A guard “true” is usually omitted together with the vertical bar.

The operational semantics of CHR can be described as a state transition system for states of the form \( G \), where \( G \) (the goal) is a conjunction of user-defined and built-in constraints.

Given a CHR program \( P \) we define the transition relation \( \rightarrow_P \) by introducing three kinds of computation steps (Figure 1).

In Figure 1, the notation \( G_{\text{built}} \) denotes the built-in constraints in a goal \( G \). An equation \( c(t_1, \ldots, t_n)=d(s_1, \ldots, s_n) \) of two constraints stands for \( t_1=s_1 \land \ldots \land t_n=s_n \) if \( c \) and \( d \) are the same predicate symbols and for false otherwise. An equation \( (p_1 \land \ldots \land p_n)=(q_1 \land \ldots \land q_m) \) stands for \( p_1=q_1 \land \ldots \land p_n=q_n \) if \( n=m \) and for false otherwise. Conjunctions can be permuted since conjunction is associative and commutative.

Solve

\[
\text{If} \quad CT \models \forall (G_{\text{built}} \leftrightarrow G'_{\text{built}}) \\
\text{and} \quad G' \text{ is the "normal form" of } G \\
\text{then} \quad G \rightarrow_P G'
\]

Simplify

\[
\text{If} \quad (H \leftrightarrow C \mid B) \text{ is a rule with variables } \bar{x} \\
\text{and} \quad CT \models \forall (G_{\text{built}} \rightarrow \exists \bar{x}(H=H' \land C)) \\
\text{then} \quad (H' \land G) \rightarrow_P (H=H' \land B \land C \land G)
\]

Propagate

\[
\text{If} \quad (H \Rightarrow C \mid B) \text{ is a rule with variables } \bar{x} \\
\text{and} \quad CT \models \forall (G_{\text{built}} \rightarrow \exists \bar{x}(H=H' \land C)) \\
\text{then} \quad (H' \land G) \rightarrow_P (H=H' \land B \land C \land H' \land G)
\]

Figure 1: Computation Steps of CHR

In the Solve computation step, the built-in solver normalizes the built-in constraints appearing in the state \( G \). To normalize the built-in constraints means to produce a new state \( G' \) that is (according to the
constraint theory CT) logically equivalent to G.

To Simplify user-defined constraints \( H' \) means to remove them from the state \( H' \land G \) and to add the body B of a fresh variant of a simplification rule \( (H \Leftrightarrow C \mid B) \) and the equation \( H = H' \) and the guard C to the resulting state G, provided \( H' \) matches the head H and the guard C is implied by the built-in constraints appearing in G. In this case we say that the rule R is applicable to \( H' \). A "variant" of a formula is obtained by renaming its variables. "Matching" means that \( H' \) is an instance of H, i.e. it is only allowed to instantiate (bind) variables of H but not variables of \( H' \). In the logical notation this is achieved by existentially quantifying only over the fresh variables \( \exists \) of the rule to be applied in the condition.

The Propagate transition is like the Simplify transition, except that it keeps the constraints \( H' \) in the state. Trivial nontermination caused by applying the same propagation rule again and again is avoided by applying a propagation rule at most once to the same constraints. A more complex operational semantics that addresses this issue can be found in [Abd97].

2.2 CHR by Example

Finite domains appeared first in CHIP [vH89] by incorporating consistency algorithms [Mac77, Mac92] into constraint logic programming. Implementing these techniques with CHR is straightforward. The constraint \( X::\text{Dom} \) means that the value for the variable \( X \) must be in the given finite domain \( \text{Dom} \).

The finite domain solver contains rules like:

\[
X::[] \Leftrightarrow \text{false}.
\]

\[
X::L1 \land X::L2 \Leftrightarrow \text{intersection}(L1, L2, L3) \land X::L3.
\]

The first rule reads: Replace the constraint \( X::[] \) by the constraint \text{false} exhibiting its inconsistency. The second rule intersects two domains for the same variable, thus tightening the domain.

The constraints \( X::[2,3,4] \) and \( X::[5,6] \) can be simplified to \( X::[] \) by the second rule. This constraint in turn simplifies to \text{false} with the first rule, so that the inconsistency of the initial constraints is exhibited.

3 Applications

Constraint Handling Rules have been used successfully in challenging applications, where other existing constraint logic programming systems could not be applied with the same results in terms of simplicity, flexibility and efficiency. In the following, we present a constraint solver written in CHR to solve the university course timetabling problem.

University course timetabling problems are combinatorial problems which consist in scheduling a set of courses within a given number of rooms and time periods. Solving a real world timetabling problem manually often requires a significant amount of time, sometimes several days or even weeks since several constraints must be taken into account.

Timetabling the courses offered at the Computer Science Department of the University of Munich requires the processing of hard and soft constraints. Hard constraints are conditions that must be satisfied, soft constraints, however, may be violated, but should be satisfied as much as possible. In practice, most constraint-based timetabling systems either do not support soft constraints [AB94] or use a branch & bound search instead of chronological backtracking [HW95, FH95]. Another approach is to adopt techniques developed to propagate hard constraints: soft constraint propagation is intended to associate values with an estimate of how selecting a value will influence solution quality, i.e. which value is known (or expected) to violate soft constraints, or the other way round, which value is known (or expected to) satisfy soft constraints. By considering estimates in value selection, one hopes that the first solution will satisfy a lot of soft constraints.

Our aim is to implement a similar approach for our timetabling problem using CHR [AM98, AM99]. The classical finite domain solver presented above is not sufficient for our needs: Since soft constraints may be violated, the values to be constrained must not be removed from the variable's domain. Moreover, when we have to choose a value for the variable during search, we must be able to decide whether a certain value is a good choice or not. Therefore, each value must be associated with an assessment. We chose to represent a domain as a list of value-assessment pairs. For example, assume the domain of \( X \) is \( [(3, 0), (4, 1), (5, -1)] \). Then \( X \) may take one of values 3, 4 and 5, whereas 4 is encouraged with assessment 1 and 5 is discouraged with assessment -1.

The solver is based on three types of constraints.

- \text{domain}(X, D)\ means\ that\ \( X \)\ must\ get\ assigned\ a\ value\ occurring\ in\ the\ list\ of\ value-assessment\ pairs\ D.

- \text{in}(X, L, W):\ Its\ meaning\ depends\ on\ the\ weight\ \( W. \)\ If\ \( W = \text{infinite}, \)\ i.e.\ if\ the\ constraint\ is\ hard,\ it\ means\ that\ \( X \)\ must\ not\ get\ assigned\ a\ value\ not\ occurring\ in\ the\ list\ \( L. \)\ If\ \( W \)\ is\ a\ number,\ i.e.\ if\ the\ constraint\ is\ soft,\ it\ means\ that\ the\ assessment\ for\ the\ values\ occurring\ in\ \( L \)\ and\ not\ yet\ removed\ from\ the\ domain\ of\ \( X \)\ should\ be\ increased\ by\ \( W. \)

- \text{notin}(X, L, W):\ If\ hard,\ means\ that\ \( X \)\ must\ not\ get\ assigned\ any\ of\ the\ values\ occurring\ in\ the\ list\ \( L. \)\ If\ it\ is\ soft,\ it\ means\ that\ the\ assessment\ for\ the\ values\ occurring\ in\ \( L \)\ and\ not\ yet\ removed\ from\ the\ domain\ of\ \( X \)\ should\ be\ decreased\ by\ \( W. \)
Propagating a soft constraint is intended to modify the assessment of the values to be constrained. For example, assume the existence of the constraint \( \text{in}(X, [3, 2]) \) stating that 3 should be assigned to X. Then we have to increase the assessment for value 3 in the domain of X by adding 2 to the current assessment of 3 obtaining the new domain \([3, 2), (4, 1), (5, -1)\] for X. However, applying a hard constraint will still mean to remove values from the variable’s domain. Consequently, an in constraint is processed by either pruning the domain or increasing the assessment for the given values.

\[
\text{domain}(X, D) \land \text{in}(X, L, W) \equiv W = \text{infinite} \\
\text{domain_intersection}(D, L, D_1) \land \\
\text{domain}(X, D_1). \\
\text{domain}(X, D), \text{in}(X, L, W) \equiv W \neq \text{infinite} \land \\
\text{increase_assessment}(W, L, D, D_1) \land \\
\text{domain}(X, D_1). \\
\text{domain}(X, D) \land \text{not in}(X, L, W) \equiv W = \text{infinite} \\
\text{domain_subtraction}(D, L, D_1) \land \\
\text{domain}(X, D_1). \\
\text{domain}(X, D) \land \text{not in}(X, L, W) \equiv W \neq \text{infinite} \land \\
\text{decrease_assessment}(W, L, D, D_1) \land \\
\text{domain}(X, D_1). \\
\text{domain}(\_, []) \equiv \text{false}. \\
\text{domain}(X, [(A, _)]) \Rightarrow X = A.
\]

We use a propagation rule instead of a simplification rule because the domain constraint must not be removed. Without it the processing of in and notin constraints imposed on the variable’s domain would not be guaranteed and thus an inconsistency might be overlooked.

In contrast to logic programming languages, CHR is a committed-choice language. That is, whenever more than one transition is possible, one transition is chosen nondeterministically (in the sense of don’t care nondeterminism, i.e., without backtracking). Furthermore, CHR performs a one-sided unification (“matching”) between goals and rule heads rather than unification. These incompatibilities make CHR difficult to use as a general-purpose logic programming language, especially for search-oriented problems. In the following, we show that a small and simple extension to CHR makes it a general-purpose constraint logic programming language: We allow disjunctions on the right hand sides of CHR rules.

So we extend the syntax of CHR: In a simplification rule \( H \iff C \mid B \) the body \( B \) is now a formula that is constructed from atoms by conjunctions and disjunctions in an arbitrary way. For the sake of uniformity the syntax of propagation rules is extended in the same way and also goals may be of the same form as a rule body. We call the extended language “CHR\(^v\)” [AS98]

The computation steps from Figure 1 will be used for CHR\(^v\) programs in the same way as they have been used for CHR programs. However, with the extended syntax disjunctions make their way into the state. In order to handle these, we introduce the Split computation step (Figure 2).

![Split](image)

Figure 2: Computation step for disjunctions

The Split step can always be applied if the state contains a disjunction. No other condition needs to be satisfied. The step leads to branching in the computation. So we get a tree rather than a chain of states.

In the two children of a state containing a disjunction this disjunction will be replaced by one or the other alternative of the disjunction, respectively.

Any Horn clause program can be converted into an equivalent CHR\(^v\) program. The central idea is to move non-committed choices and unification to the right hand sides of rules. The required transformation turns out to be Clark’s completion of logic programs [Cla78].

Consider for example the well-known ternary append predicate for lists, which holds if its third argument is a concatenation of the first and the second argument. It is usually implemented by these two Horn clauses:

\[
\text{append}([], L, L) \leftarrow \text{true}.
\text{append}([H|L_1], L_2, [H|L_3]) \leftarrow \text{append}(L_1, L_2, L_3).
\]

The corresponding CHR\(^v\) program consists of the single simplification rule

```prolog
\text{append}(\_, L, L) \leftarrow \text{false}.
\text{append}([H|L_1], L_2, [H|L_3]) \leftarrow \text{append}(L_1, L_2, L_3).
```
\[ \text{append}(X, Y, Z) \iff \\
( \text{X} = [] \land \text{Y} = 1 \land \text{Z} = 1 \\
\lor \text{X} = \{H \mid 1\} \land \text{Y} = 2 \land \text{Z} = \{H \mid 3\} \land \\
\text{append}(L1, L2, L3) ). \]

CHR\textsuperscript{\textdagger} supports a new programming style where top-down evaluation, bottom-up evaluation, and constraint solving can be interleaved in a single language. Examples for mixing logic programming paradigms using CHR\textsuperscript{\textdagger} can be found in [AS98].

5 Conclusion

In this paper, we have argued that CHR is a good vehicle for implementing application-oriented constraint solvers to solve hard real-world problems. Simplicity, flexibility, efficiency, and rapid prototyping are the advantages of using CHR.

Furthermore, we have presented the language CHR\textsuperscript{\textdagger}, a simple extension of Constraint Handling Rules. CHR\textsuperscript{\textdagger} introduces disjunctions into the bodies of rules and into the goals. We have seen that CHR\textsuperscript{\textdagger} retains the extra features of CHR, e.g., committed choice and matching, by performing the unification on the right hand side of a rule and by doing backtracking within a single rule rather than between rules. With this programming style, several paradigms, e.g. top-down evaluation, bottom-up evaluation and constraint solving can be interleaved in a single language.
